In classical physics an orbiting electron doesn't radiate energy because the total acceleration at the electron is zero.

Also an electron at rest in a gravitational field doesn't radiate because the total acceleration is zero.

When an electron accelerates it emits a photon.

When the electron decelerates it absorbs a photon.

In hydrogen atom the change of orbits are accelerations and decelerations.

The Larmor formula is wrong:

$$P = \frac{q^2 a^2}{6\pi \epsilon_0 c^3}$$

Correct formulas:

Force:

$$F = m_e a$$

m_e - Electron mass; a – Acceleration; c – Light speed.

Power:

$$P = Fc \quad \Leftrightarrow \quad P = m_e c a$$

Intensity:

$$I = P / 4\pi R^2 \quad ; \quad R = 1\text{m}$$

$$I = \frac{m_e c a}{4\pi}$$

Approximate values for hydrogen:

$$F = \frac{13.6 \times 2\pi}{137x_e} = 4.12 \times 10^{-8} N = m_e a$$

$$\Leftrightarrow a = 4.52 \times 10^{22} = \frac{\pi \cdot c^2}{137^3 x_e} ; \quad \Delta t = \frac{137^2 x_e}{2\pi \cdot c}$$

$$P = 12.35W ; \quad I = 0.983W/m^2$$

$$\text{For } R = R_e = \frac{137x_e}{2\pi} \quad \Leftrightarrow \quad I = 3.51 \times 10^{20} W/m^2$$

Intensity:

$$I = \frac{m_e c a}{4\pi} \quad \text{and} \quad a = \frac{\Delta v}{\Delta t}$$

$$\Delta v = \frac{c}{137} \left(\frac{1}{n_1} - \frac{1}{n_2} \right)$$

$$\lambda = n137x_e \quad ; \quad v = \frac{c}{n137}$$

$$t = \frac{\lambda}{v} = \frac{n^2 137^2 x_e}{c}$$

$$\Delta t = \frac{137^2 x_e}{c} (n_1^2 - n_2^2) \frac{137}{2\pi} ; \quad x_e - \text{Electron Compton wavelength.}$$

$$a = \frac{2\pi \cdot c^2}{137^4 x_e n_1 n_2 (n_1 + n_2)}$$

$$I = \frac{m_e c}{4\pi} \frac{2\pi \cdot c^2}{137^4 x_e n_1 n_2 (n_1 + n_2)}$$

This is not correct but the correct solution is very near.
This is the way we must go.
